

Physics 42200 Waves & Oscillations

Lecture 38 – Diffraction

Spring 2013 Semester

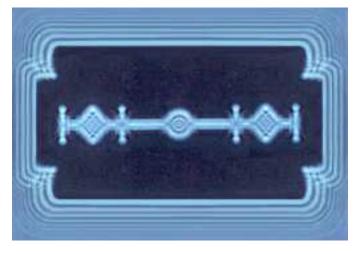

Matthew Jones

Diffraction

"Light transmitted or diffused, not only directly, refracted, and reflected, but also in some other way in the fourth, *breaking*."

Huygens-Fresnel Principle

Huygens:

 Every point on a wave front acts as a point source of secondary spherical waves that have the same phase as the original wave at that point.

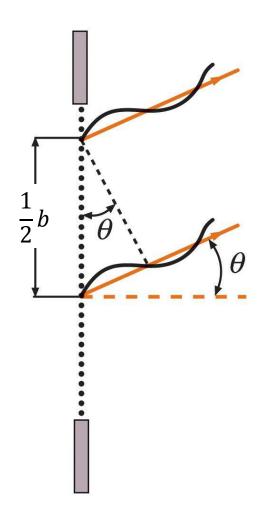

Fresnel:

 The amplitude of the optical field at any point in the direction of propagation is the superposition of all wavelets, considering their amplitudes and relative phases.

Examples with water waves

- Wide slit: waves are unaffected
- Narrow slit: source of spherical waves
- In between: multiple interfering point sources

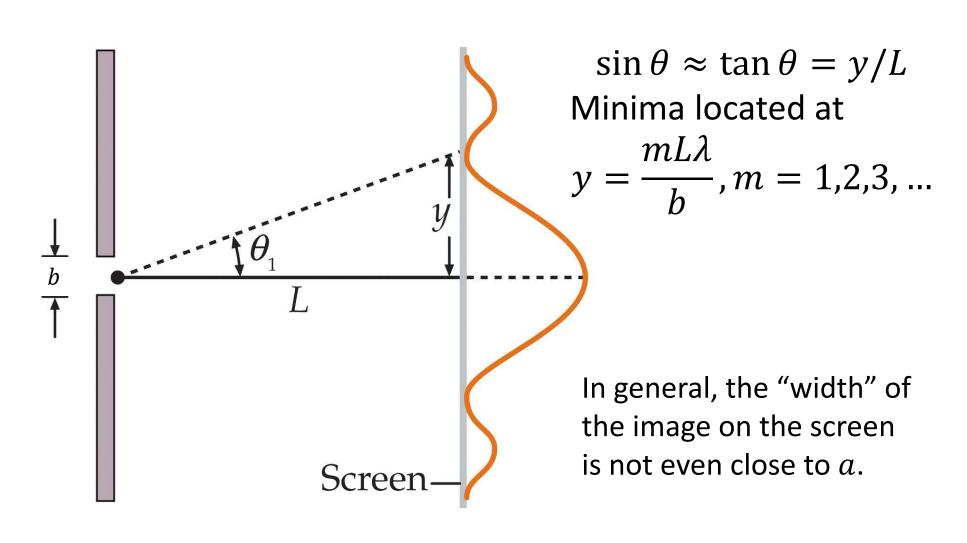

Think of the slit as a number of point sources with equal amplitude. Divide the slit into two pieces and think of the interference between light in the upper half and light in the lower half.

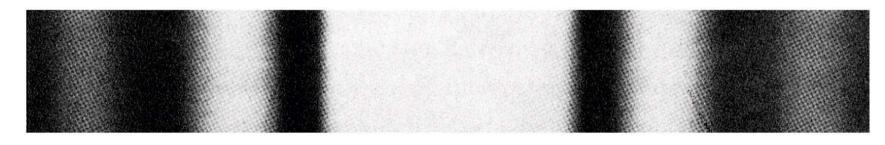

Destructive interference when

$$\frac{b}{2}\sin\theta = \frac{\lambda}{2}$$

Minima when

$$\sin\theta = \frac{\lambda}{b}$$

Minima located at

$$\sin \theta = \frac{mL\lambda}{b}$$
, $m = 1,2,3,...$

Minima only occur when $b > \lambda$.

Intensity

Waves from all points in the slit travel the same distance to reach the center and are in phase: constructive interference.

$$\frac{\lambda}{a}$$

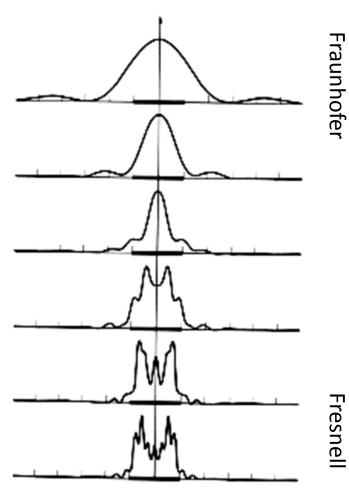

$$\frac{2\lambda}{a}$$

Fresnel and Fraunhofer Diffraction

Assumptions about the wave front that impinges on the slit:

 When it's a plane, the phase varies linearly across the slit: Fraunhofer diffraction

 When the phase of the wave front has significant curvature: Fresnel diffraction

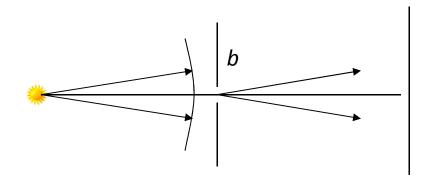

Fresnel and Fraunhofer Diffraction

- Fraunhofer diffraction
 - Far field: $R \gg b^2/\lambda$

 R is the smaller of the distance to the source or to the screen

- Fresnel Diffraction:
 - Near field: wave front is not a plane at the aperture

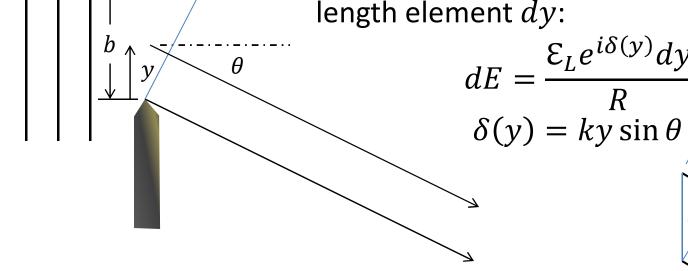

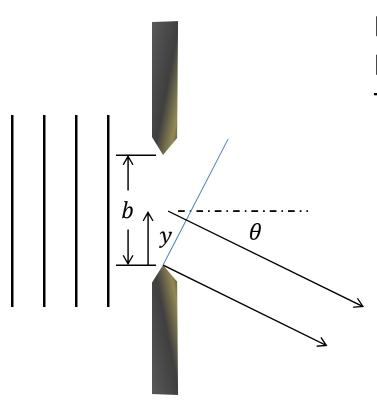

Light with intensity I_0 impinges on a slit with width *b*

Electric field at a distance R due to the length element dy:

$$dE = \frac{\mathcal{E}_L e^{i\delta(y)} dy}{R}$$
$$\delta(y) = ky \sin \theta$$

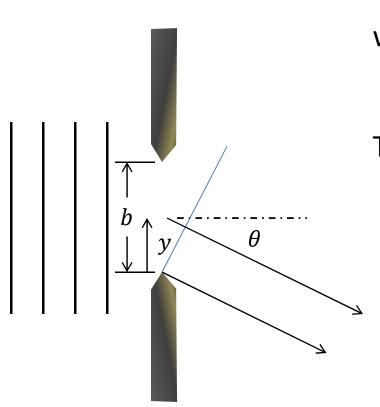

$$dE = \frac{\mathcal{E}_L e^{iky \sin \theta} dy}{R}$$

Let y = 0 be at the center of the slit. Integrate from -b/2 to +b/2: Total electric field:

$$E = \frac{\mathcal{E}_L}{R} \int_{-b/2}^{+b/2} e^{iky \sin \theta} dy$$

$$= \frac{\mathcal{E}_L}{R} \frac{e^{i(kb/2) \sin \theta} - e^{-i(kb/2) \sin \theta}}{ik \sin \theta}$$

$$= \frac{\mathcal{E}_L b}{R} \frac{\sin \left(\frac{1}{2} ka \sin \theta\right)}{\frac{1}{2} kb \sin \theta}$$

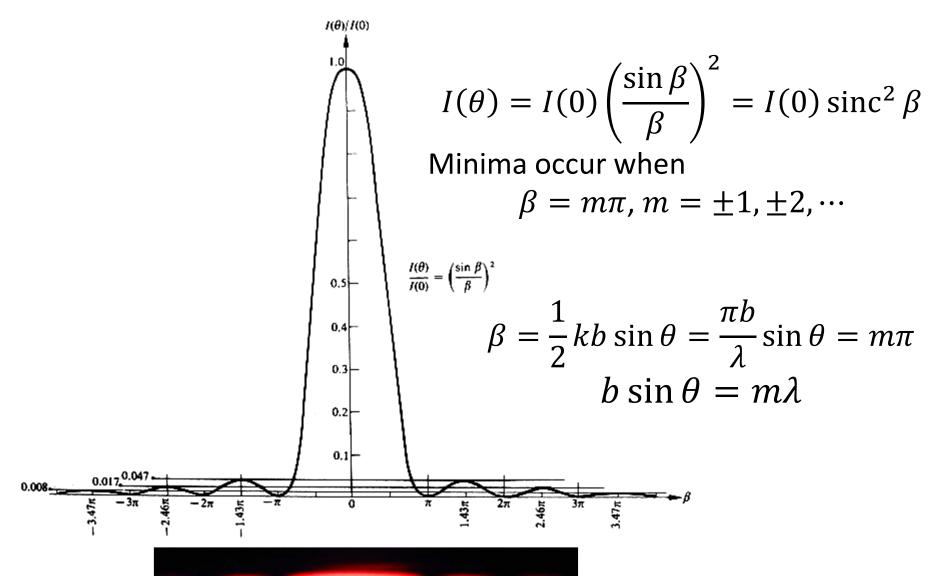

$$E = \frac{\mathcal{E}_L b}{R} \frac{\sin \beta}{\beta}$$

where

$$\beta = \frac{1}{2}kb\sin\theta$$

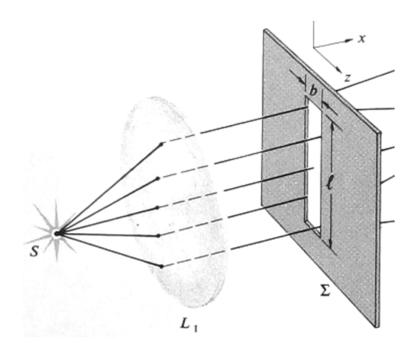

The intensity of the light will be

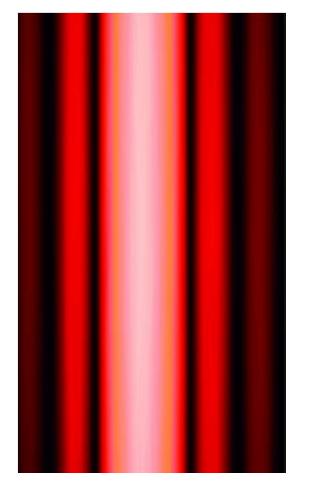

$$I(\theta) = I(0) \left(\frac{\sin \beta}{\beta}\right)^{2}$$
$$= I(0) \operatorname{sinc}^{2} \beta$$

Single slit: Fraunhofer diffraction

Adding dimension: long narrow slit Diffraction most prominent in the narrow direction.

Emerging light has cylindrical symmetry

Rectangular Aperture Fraunhofer Diffraction

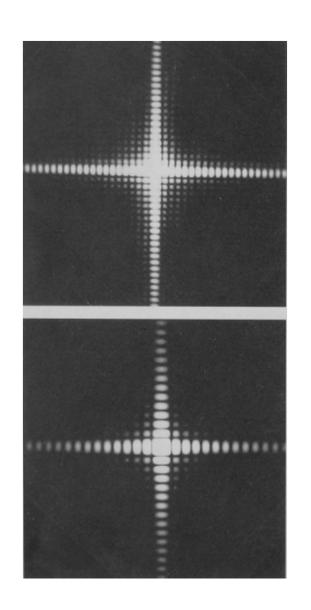

Source strength per unit area: \mathcal{E}_A

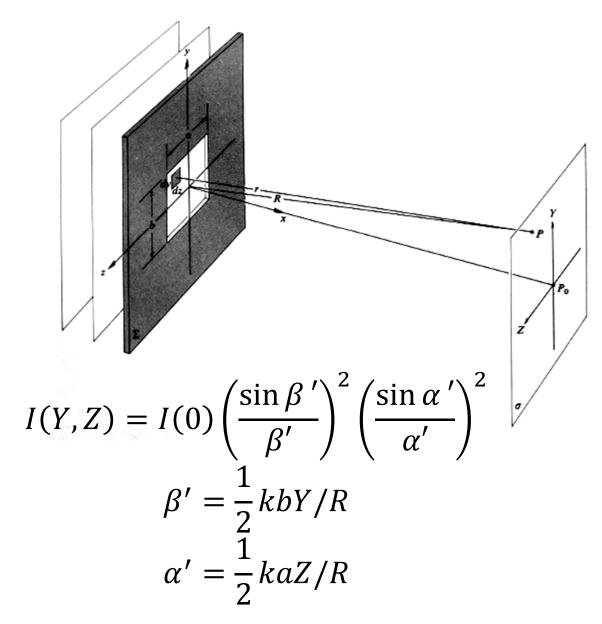

$$dE \approx \frac{\mathcal{E}_L e^{ikyY/R} e^{ikzZ/R} dy dz}{R}$$

$$E = \frac{\mathcal{E}_L}{R} \left(\int_{-b/2}^{+b/2} e^{ikyY/R} dy \right) \left(\int_{-a/2}^{+a/2} e^{ikzZ/R} dz \right)$$

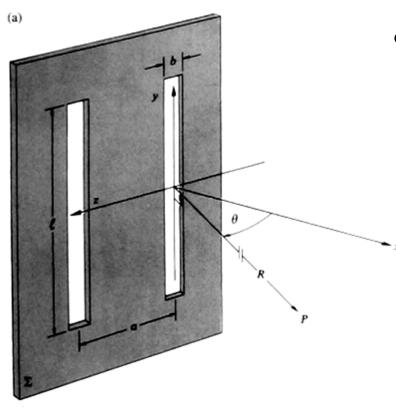

$$I(Y,Z) = I(0) \left(\frac{\sin \beta'}{\beta'} \right)^2 \left(\frac{\sin \alpha'}{\alpha'} \right)^2$$

Rectangular Aperture

Double-Slit Fraunhofer Diffraction

 Same idea, but this time we integrate over two slits:

$$E = \frac{\mathcal{E}_L}{R} \int_{-b/2}^{+b/2} e^{iky \sin \theta} dy$$

$$+ \frac{\mathcal{E}_L}{R} \int_{a-b/2}^{a+b/2} e^{iky \sin \theta} dy$$

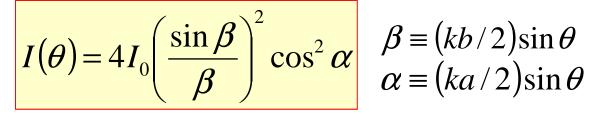

$$= \frac{\mathcal{E}_L b}{R} \frac{\sin \beta}{\beta} (1 + e^{ika \sin \theta})$$

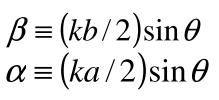

Double-Slit Fraunhofer Diffraction

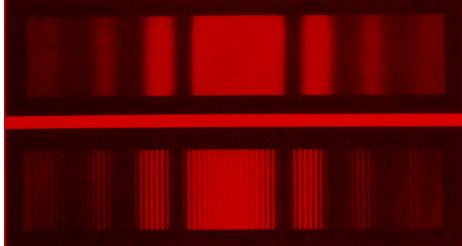

Since a > b, $\cos \alpha$ oscillates more rapidly than $\sin \beta$

Double Slit: Fraunhofer Diffraction

Minima: $\alpha = \pm \pi/2, \pm 3\pi/2$

$$a\sin\theta = (m+1/2)\lambda$$

or: $\beta = m\pi$, where $m = \pm 1, \pm 2...$

$$b\sin\theta = m\lambda$$
