PURDUE UNIVERSITY DEPARTMENT OF PHYSICS

Physics 53600

Electronics Techniques for Research

Now in PowerPoint!

Spring 2020 Semester

Prof. Matthew Jones

ANNOUNCEMENT

- Obvious changes to the course:
  - No in-person lectures: you'll have to read the lecture notes yourself
  - No more labs: don't worry about it – your grade will be based on work done so far
  - Remaining assignments will try to cover topics that would have been explored in the lab
  - Second mid-term: simplest to cancel it
  - Final exam: I'm not sure what to do about this yet, but I'll figure something out.
- Changes to grading scheme:
  - Old scheme: Assignments (30%) exams (40%) lab (30%)
  - New scheme: Assignments (50%) exams (25%) lab (25%)

ANNOUNCEMENT

- Because there won't be any in-person lectures, you will have to read the lecture notes yourself.
- To demonstrate that you have read them, you will be required to answer *one or two simple questions* before the next lecture is posted.
- The question will be somewhere (like maybe at the end?) and you just have to e-mail me the answer

  mjones@physics.purdue.edu
- To make this easy, please make your subject look like this:

  "PHYS53600 Lecture xx questions Your Name"
- These will be part of your assignment grade, maybe contributing 10% of your total grade.

LECTURE 19 QUESTION #1

What are four ways that can be used to increase channel capacity?

LECTURE 19 QUESTION #2

Although the SPI interface might not necessarily be very fast, what are some of its advantages?

Digital Data Transmission

- The speed of digital circuits is often limited by the error-free rate at which data can be transferred
- This includes transmission on all length scales:
  - Communication with Voyager 2 (10^{13} m)
  - Trans-oceanic cables (10^{6} m)
  - Commercial network infrastructure (10^{3} m)
  - Peripheral interfaces (1 m)
  - Computer backplanes (10^{-1} m)
  - Printed circuit board interconnects (10^{-2} m)
  - Within an integrated circuit (10^{-3} m)

Digital Data Transmission

- Fundamental limit is described by Shannon's Channel Capacity Theorem:

$$c = b \log_2(1 + s)$$

- Where
  - c is the error-free single-channel capacity (eg. in bits per second)
  - b is the bandwidth of the channel
  - s is the signal-to-noise ratio

Digital Data Transmission

- There are several obvious ways to increase the rate at which data can be transferred:
  - Increase the bandwidth
    - Low bandwidth example: smoke signals
    - High bandwidth example: shielded coaxial cable
  - Increase the signal-to-noise ratio
    - Either increase the amplitude of the signal or reduce the amplitude of the noise
  - Detect and correct errors in data transmission
  - Increase the number of channels

Examples

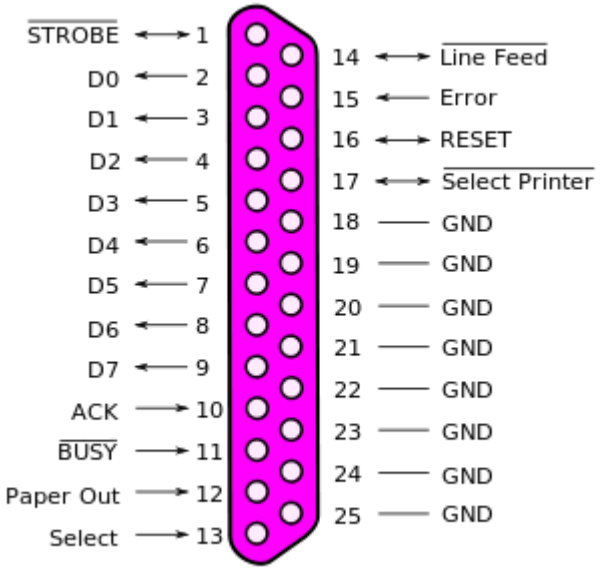
- There are many examples, but many of them are now obsolete because of their fundamental channel capacity limitations
- They still serve as useful examples because they are easy to understand and analyze

Parallel Printer Interface

- The parallel printer interface was developed in the 1970's and was only superseded by other interfaces (like USB) in the 1990's.
- It was more-or-less standardized which allowed many manufacturers to design compatible equipment.
- The standard specified both the electrical and physical interfaces.

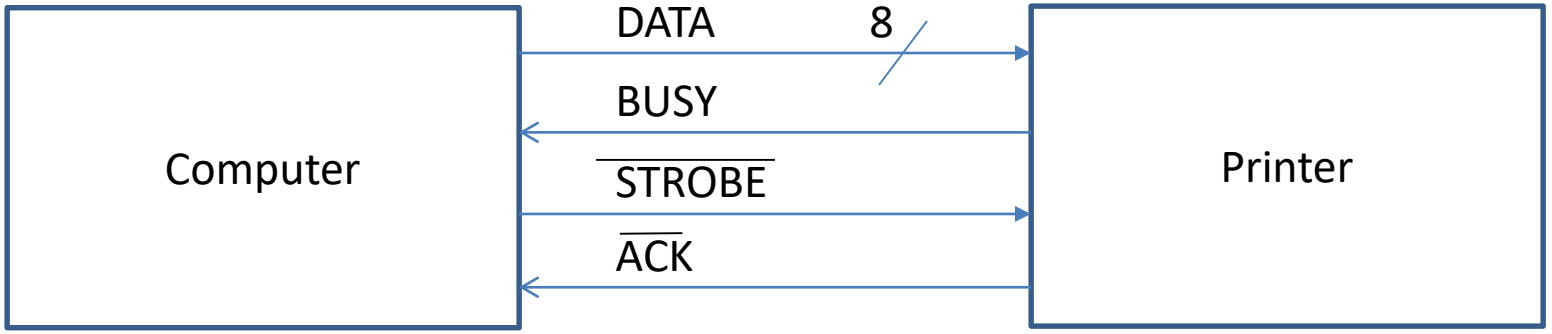
Parallel Printer Interface

- Physical interface:
  - 25-pin connector (DB-25)
  - 25-conductor cable
- Electrical interface:
  - 8 parallel data signals
  - Several control signals
  - Lots of ground signals
  - Also specifies voltages (5 volt TTL logic levels)

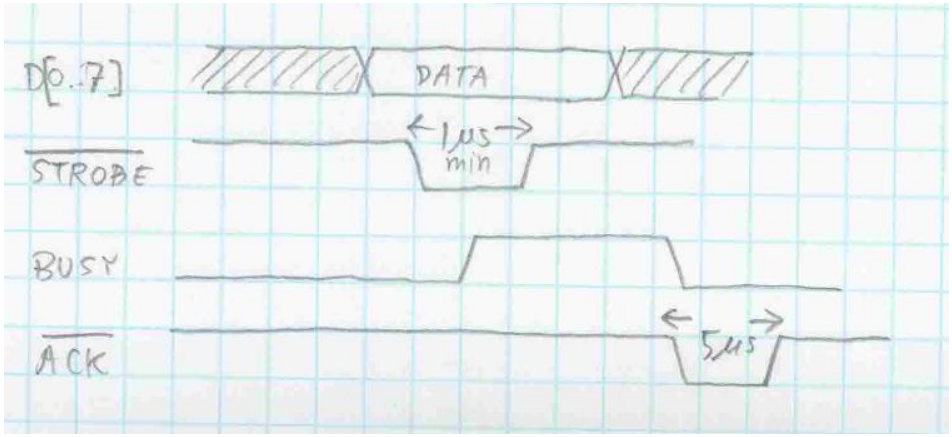


Parallel Printer Interface

- Most communications could be achieved using only three control signals:



- Timing diagram:



Parallel Printer Interface

- Maximum data transfer rate:
  - With this specification, the rate cannot be greater than about 150 kBytes per second.
  - Alternative specifications allowed rates of up to about 500 kBytes per second.
- Disadvantages:
  - Expensive cables (25 conductors)
  - 5 volt single-ended signals (generate RF noise)
  - Slow hand-shaking mechanism
- Fundamental data synchronization mechanism:
  - $\overline{\text{STROBE}}$ indicates when it is safe to sample DATA

Memory Interface

- Just because the parallel interface became obsolete for peripherals (like printers) doesn't mean that the concepts are not still widely used!
- In many cases this is still a very practical way to transfer data over short distances
  - Between integrated circuits on a printed circuit board
  - Between peripheral cards on a bus (like the older-generation PCI bus used in many PC's)

Memory Interface

- For example, consider the CY7C1020CV33 memory chip (32k x 16 bit static RAM)…
- Signal interface:
  - Input address: $A_{0..14}$
  - Data input/output: $D_{0..15}$
  - Chip enable input: $\overline{CE}$
  - Write enable input: $\overline{WE}$
  - Output enable: $\overline{OE}$
- Similarity with the parallel printer interface:
  - One signal (WE or OE) is used to indicate when it is safe to sample the address/data signals

Memory Interface

Features

- **Pin- and function-compatible with CY7C1020V33**
- **High speed**
  - **—t_{AA} = 10, 12, 15 ns**
- **CMOS for optimum speed/power**
- **Low active power**
  - **—360 mW (max.)**
- **Automatic power-down when deselected**
- **Independent control of upper and lower bits**
- **Available in 44-pin TSOP II**

Functional Description

The CY7C1020CV33 is a high-performance CMOS static RAM organized as 32,768 words by 16 bits. This device has an automatic power-down feature that significantly reduces power consumption when deselected.

Writing to the device is accomplished by taking Chip Enable ($\overline{CE}$) and Write Enable ($\overline{WE}$) inputs LOW. If Byte Low Enable ($\overline{BLE}$) is LOW, then data from I/O pins (I/O_1 through I/O_8), is written into the location specified on the address pins (A_0 through A_{14}). If Byte High Enable ($\overline{BHE}$) is LOW, then data from I/O pins (I/O_9 through I/O_{16}) is written into the location specified on the address pins (A_0 through A_{14}).

Reading from the device is accomplished by taking Chip Enable ($\overline{CE}$) and Output Enable ($\overline{OE}$) LOW while forcing the Write Enable ($\overline{WE}$) HIGH. If Byte Low Enable ($\overline{BLE}$) is LOW, then data from the memory location specified by the address pins will appear on I/O_1 to I/O_8. If Byte High Enable ($\overline{BHE}$) is LOW, then data from memory will appear on I/O_9 to I/O_{16}. See the truth table at the back of this data sheet for a complete description of read and write modes.

The input/output pins (I/O_1 through I/O_{16}) are placed in a high-impedance state when the device is deselected ($\overline{CE}$ HIGH), the outputs are disabled ($\overline{OE}$ HIGH), the $\overline{BHE}$ and $\overline{BLE}$ are disabled ($\overline{BHE}$, $\overline{BLE}$ HIGH), or during a write operation ($\overline{CE}$ LOW, and $\overline{WE}$ LOW).

The CY7C1020CV33 is available in standard 44-pin TSOP Type II packages.

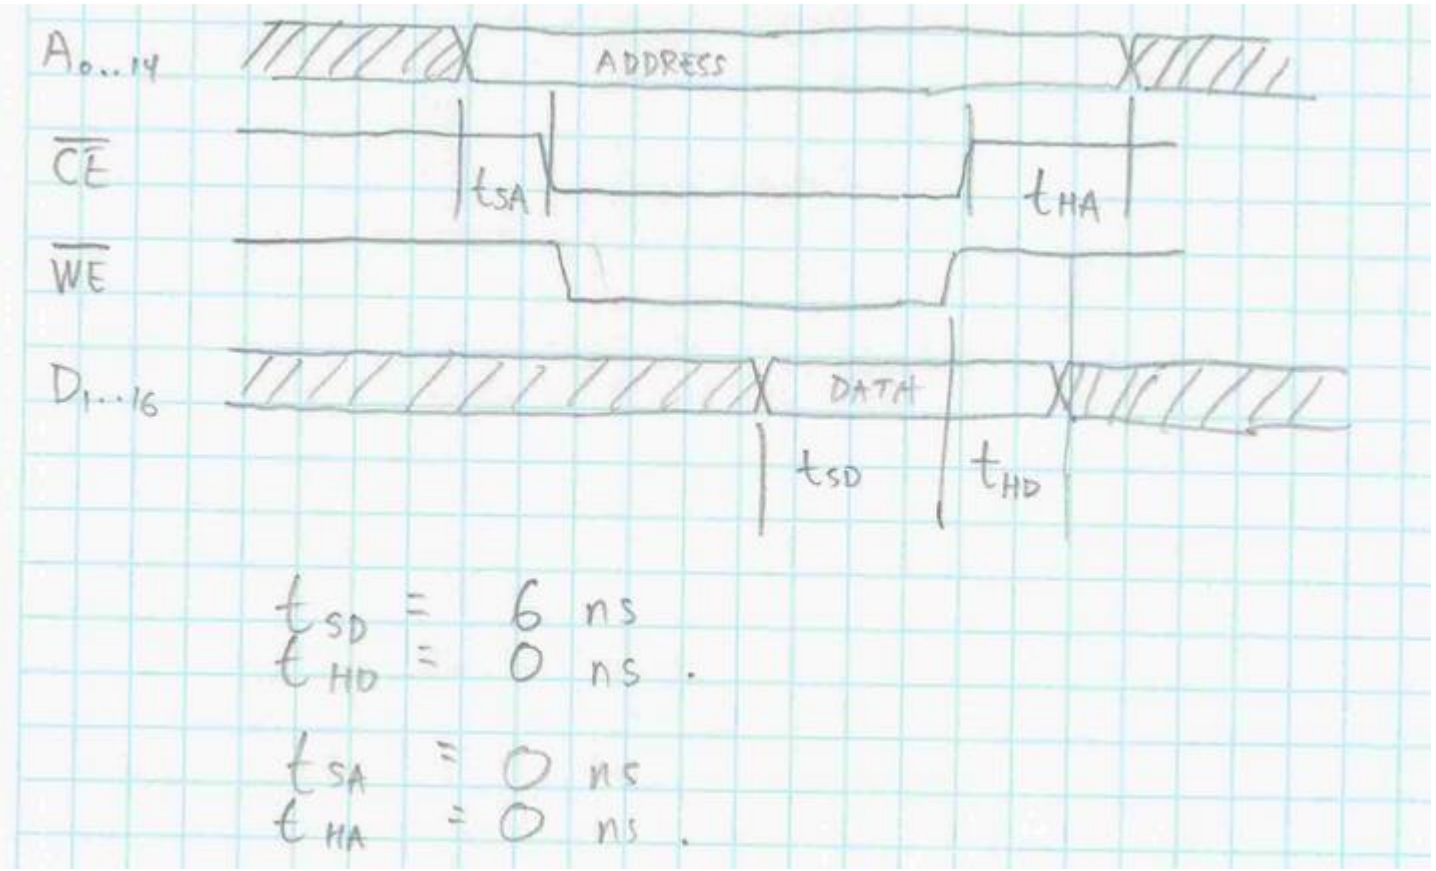
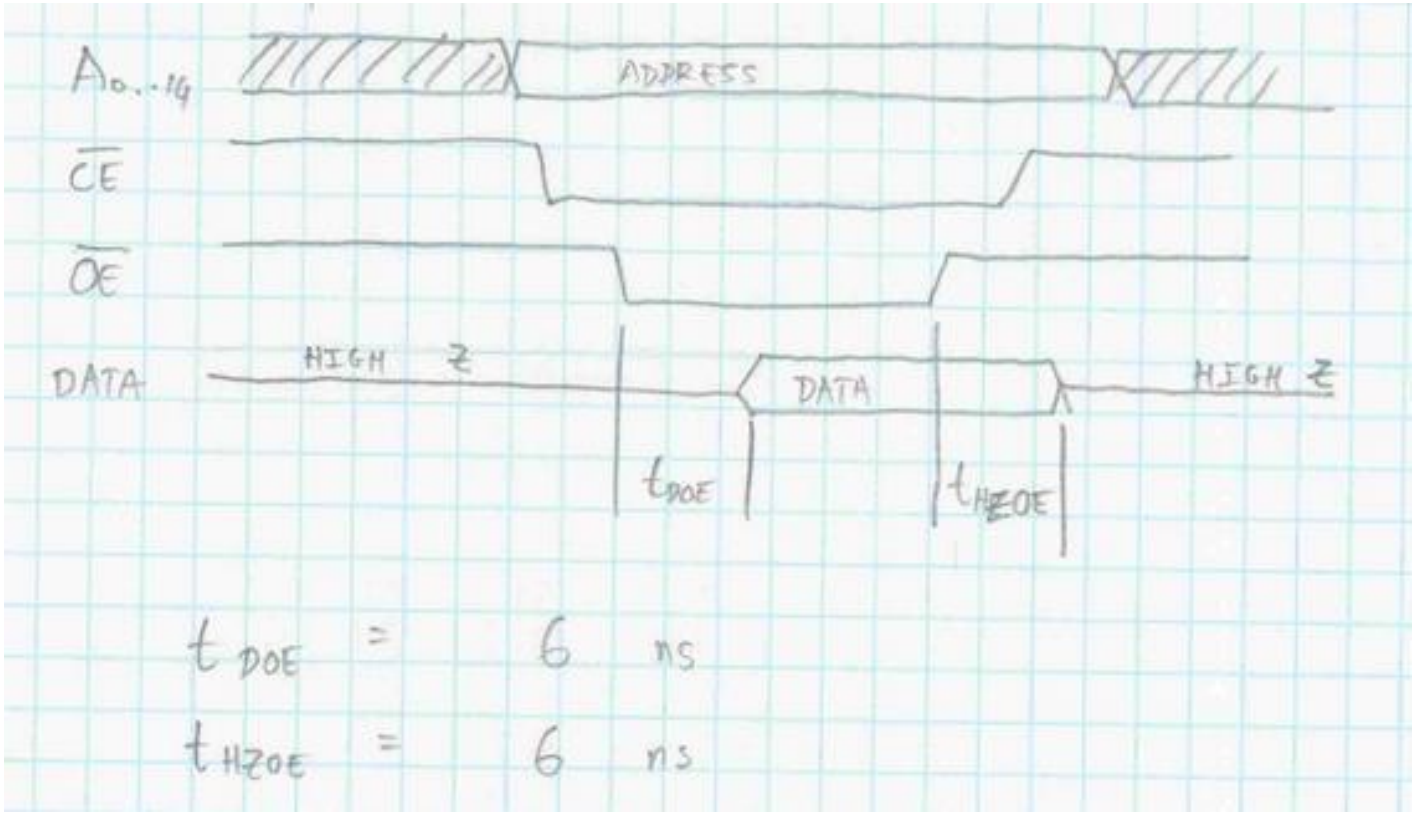
Memory Interface

- Write operation:



Memory Interface

- Read operation:

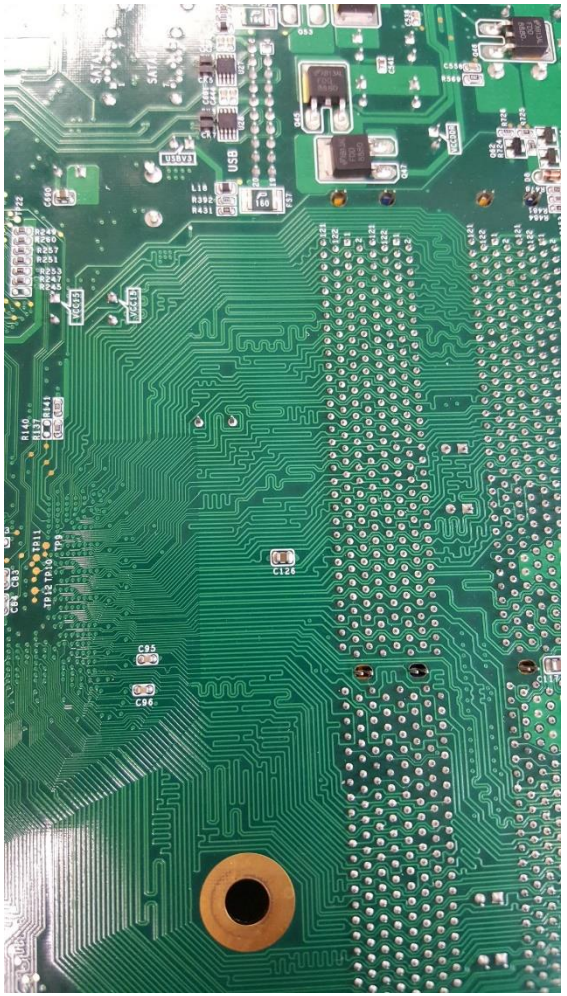


Memory Interfaces

- What is the maximum data transfer rate when writing?
- In principle, you could transfer 16 bits every 6 ns… this would be 2.667 Gbits per second.
- In practice it will be slower…
  - The signals on all the data lines might not all arrive at the same time (skew)
  - Propagation speed is about ½ c
  - Electrical connections that are physically close need extra delay (extra length) added so that all signals arrive at the same time

Correcting for Signal Skew

- You can see examples of this on most modern PCB layouts.
- The modelling of high-speed signals on printed circuit boards can be a very important part of the design process.



Serial Data Transfer

- Sometimes, high data transfer rates are not required and parallel interfaces present some disadvantages:
  - They require lots of physical resources (lots of pins on components, lots of wires in cables, lots of board space for routing)
- When data rates are not critical it can be convenient to transfer data one bit at a time.
  - This requires a data format specification

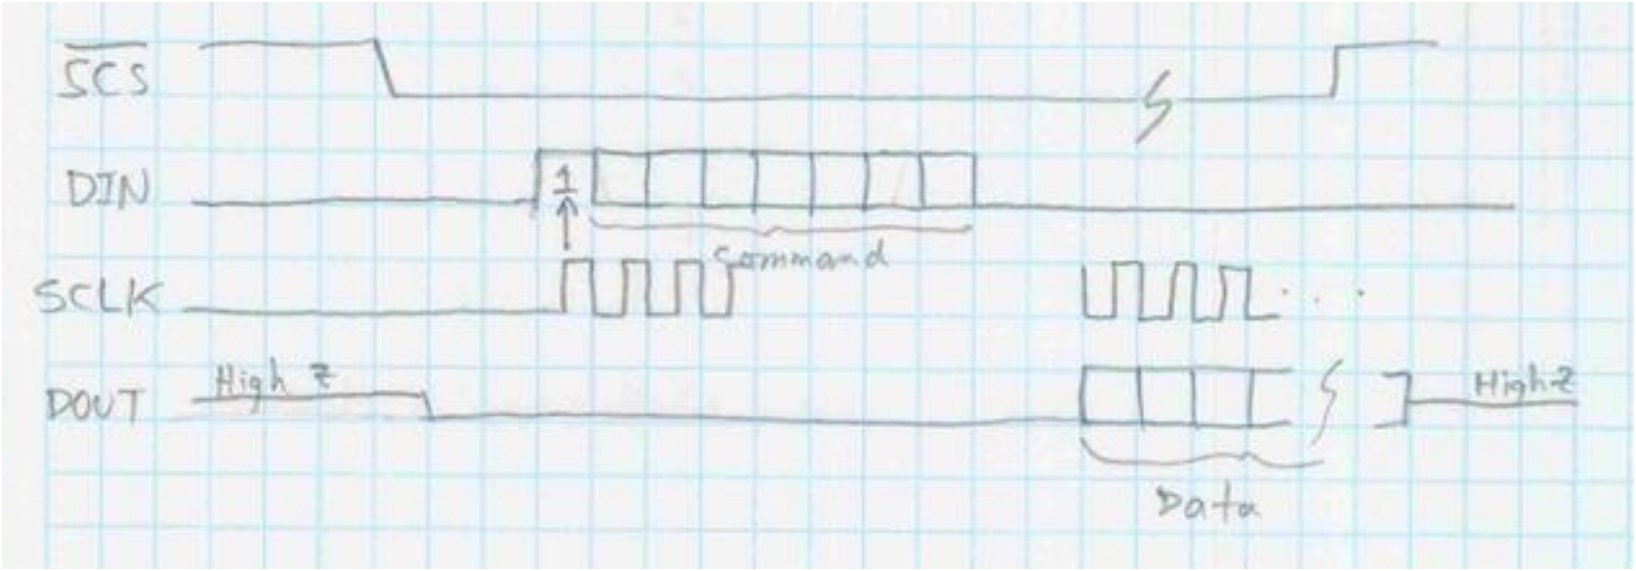
Serial Peripheral Interface

- The SPI interface is quite simple and is basically a standard for many integrated circuits that have internal registers that need to be programmed
  - Examples of actual devices that use the SPI interface will follow…
- The SPI interface (usually) has 4 signals:
  - SDIN (serial data in)
  - SDOUT (serial data out)
  - SCLK (serial clock)
  - $\overline{\text{SCS}}$ (serial chip select – active low)

SPI Interface

- Electrical specification:
  - When $\overline{SCS}$ is high (de-asserted), then SDOUT will be in a high impedance state.
  - This allows many devices to share the SDIN/SDOUT/SCLK signals provided ONLY ONE has $\overline{SCS}$ low at any given time.
  - Data is sampled on the rising edge of SCLK
  - SCLK doesn't have to have a fixed frequency
- This isn't really a formal standard, but it's simple enough that it is not hard to implement correctly.

Example SPI Interface



- SDIN is sampled on the rising edge of SCLK.
- The first ‘1’ bit after SCS goes low indicates the start of a “command” (for example - this is not always the case).
- If the command results in data being transferred out, it will appear on SDOUT.
- SDOUT is asserted on the falling clock edge so that the host can sample it on the rising clock edge.

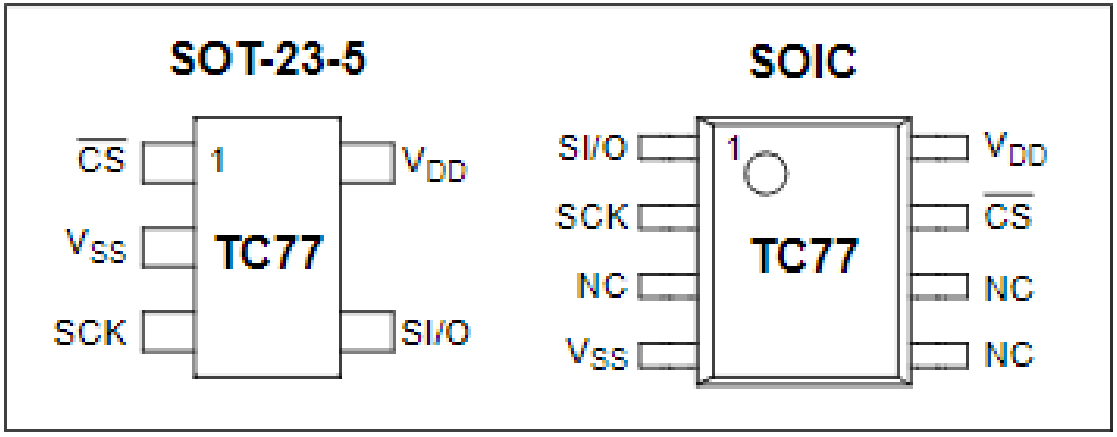
Thermal Sensor with SPI Interface

Package Types



SPI Interface Example

- Reading the temperature:

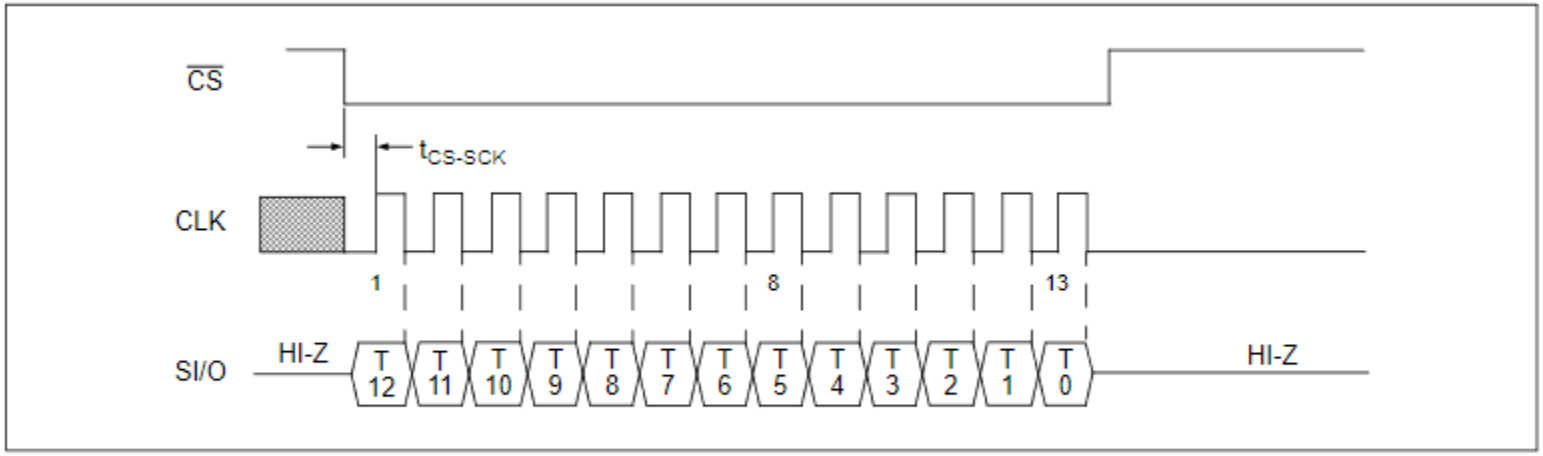


FIGURE 3-2: *Temperature Read Timing Diagram - (Reading only the first 13 Bits of the Temperature Register).*

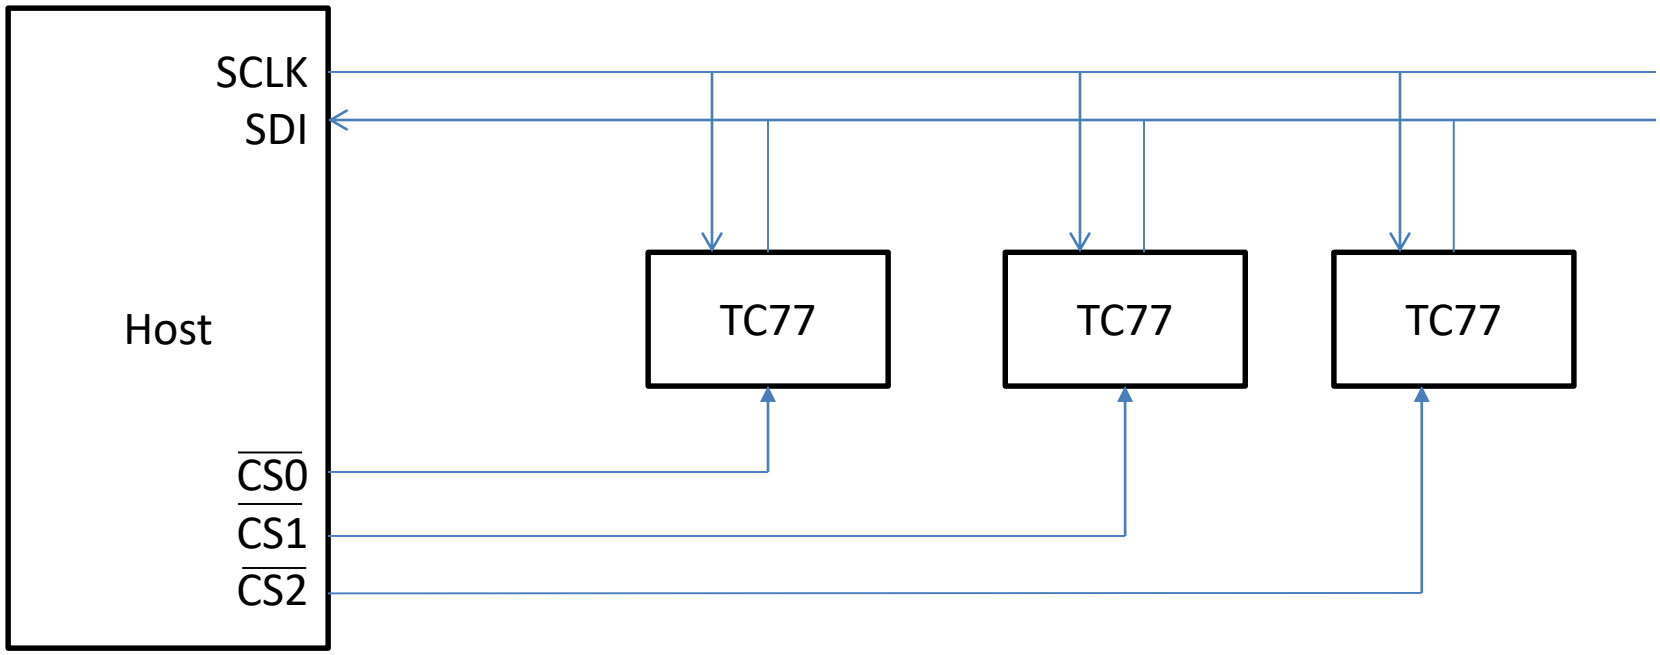
SPI Interface Example

- You can connect many devices to the same bus and talk to them individually using different $\overline{CS}$ signals:



Example: SD memory interface

- Secure Digital Memory Cards (SD cards) can be used with an SPI interface:

SDC

No	SD	SPI
8	DAT1	
7	DAT0	DO
6	Vss2	
5	CLK	SCLK
4	Vcc	
3	Vss1	
2	CMD	DI
1	CAT3	CS
9	DAT2	

MMC

No	MMC	SPI
7	DAT	DO
6	Vss2	
5	CLK	SCLK
4	Vcc	
3	Vss1	
2	CMD	DI
1	RES	CS

- In this case we only care about the DO, SCLK, DI and CS signals.

SD Memory Interface

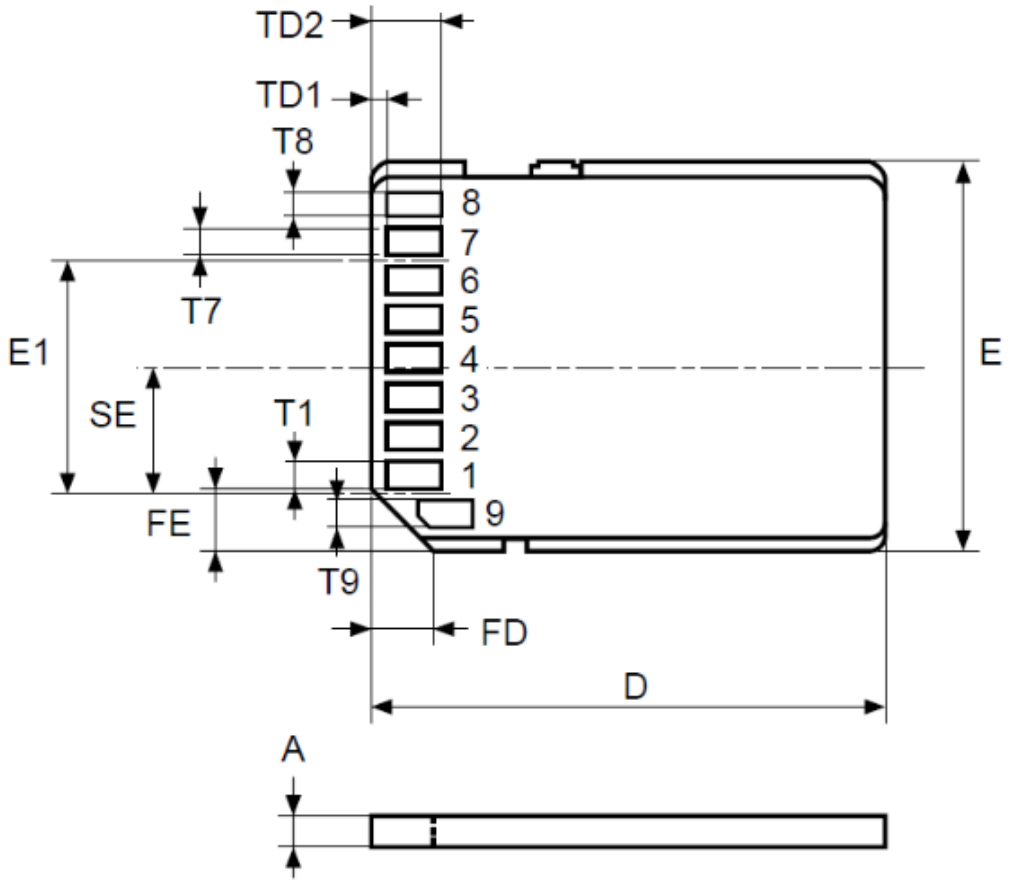
- The interface must be a standard to ensure interoperability of all SD cards and devices.
- One example of a complete specification can be found here:

https://media.digikey.com/pdf/Data%20Sheets/Viking%20PDFs/PSFSD3yyyyQyyyy.pdf

- These devices have two operating modes (SD mode and SPI mode) but we will only focus on the SPI mode.

SD Card Mechanical Interface

Figure 5-1: 2.5” SD Case Dimensions: 24mm (W) x 32mm (L) x 2.1mm (H)



Note: Drawing is not to scale

SD Card Physical Interface

4.1.1 SD Bus Pin Assignment

Table 4-1: SD Bus Pin Assignment

Pin #	SD Mode			SPI Mode		
	Name	Type[1]	Description	Name	Type[1]	Description
1	CD/DAT3[2]	I/O/PP[3]	Card Detect/ Data Line [Bit 3]	CS	I[3]	Chip Select (neg true)
2	CMD	I/O/PP	Command/Response	DI	I	Data In
3	VSS1	S	Supply voltage ground	VSS	S	Supply voltage ground
4	VDD	S	Supply voltage	VDD	S	Supply voltage
5	CLK	I	Clock	SCLK	I	Clock
6	V_{SS2}	S	Supply voltage ground	V_{SS2}	S	Supply voltage ground
7	DAT0	I/O/PP	Data Line [Bit 0]	DO	O/PP	Data Out
8	DAT1	I/O/PP	Data Line [Bit 1]	RSV		
9	DAT2	I/O/PP	Data Line [Bit 2]	RSV		

SD Card SPI Interface

- Data transfer is performed as previously described.
  - there is a command sent to the DI input…
  - …possibly followed by additional data
  - Data is read back from the DO output.
- All that remains to be specified is how to send commands and interpret the data that is sent back.
- You can find examples of the standard set of commands online
  - They consist of things like, “initialize”, “block read”, and “block write”
